14. ABSTRACT Calculations are presented of vibrational absorption spectra for energy minimized structures of PCE-nH ₂ O, TCE-nH ₂ O, DCE-nH ₂ O, and VC-nH ₂ O molecular clusters using density function theory (DFT). DFT can provide interpretation of absorption spectra with respect to molecular structure for excitation by electromagnetic waves at frequencies within the IR range. The absorption spectrum corresponding to excitation states of these molecular clusters, which consist of relatively small numbers of atoms, should be associated with response features that are intermediate between that of isolated molecules and that of bulk systems. DFT calculated absorption spectra represent quantitative estimates that can be correlated with additional information obtained from laboratory measurements. The DFT software GAUSSIAN was used for the calculations of excitation states presented here.

Introduction

The properties of PCE- $n\text{H}_2\text{O}$, TCE- $n\text{H}_2\text{O}$, DCE- $n\text{H}_2\text{O}$ and VC- $n\text{H}_2\text{O}$ molecular clusters are of major importance for monitoring and detection of chlorinated hydrocarbons in water. This follows in that tetrachloroethylene (PCE), trichloroethylene (TCE), dichloroethylene (DCE) and vinyl chloride (VC), which are part of a specific chemical transformation sequence ending in ethene, are among toxic and carcinogenic contaminants commonly found in the environment, e.g., ground water. The transformation sequence for PEC to ethane is shown in Fig. (1). The detection of these hydrocarbons, especially in the presence of water, using methods based on infrared (IR) spectroscopy is of particular interest. Specifically, IR spectral signatures, i.e., fingerprint spectra, can be correlated with the presence of these hydrocarbons (see reference [1]). Accordingly, the molecular structure and IR absorption spectra of these clusters is important for understanding the scattering and absorption of radiation transmitted through ambient environments, which is for purposes of detecting target materials of interest. For example, detection methodologies using lasers require knowledge of IR absorption spectra associated with different types of ambient molecules, e.g., H_2O , in order to apply background subtraction or spectral-signature-correlation algorithms, which would enhance spectral features associated with specific materials targeted for detection. The present study presents investigation of structures and properties of PCE- $n\text{H}_2\text{O}$, TCE- $n\text{H}_2\text{O}$, DCE- $n\text{H}_2\text{O}$ and VC- $n\text{H}_2\text{O}$ molecular clusters using DFT. The molecular-level dielectric response of these clusters, within the IR range of frequencies for vibrational excitation by electromagnetic waves, should be of interest for interpretation of spectral signatures associated with detection methodologies.

Density functional theory (DFT) is applied to determine energy optimized structures and absorption spectra for PCE- $n\text{H}_2\text{O}$, TCE- $n\text{H}_2\text{O}$, DCE- $n\text{H}_2\text{O}$ and VC- $n\text{H}_2\text{O}$ molecular clusters. DFT applied for the determination of equilibrium molecular structures and absorption spectra provides information complementary to that of experimental results. In this study, DFT calculated vibrational modes are associated with different structures of molecular clusters. In particular, DFT is used for calculation of ground state resonance structure to enable physical interpretation of absorption spectra associated with molecular structures excited by IR electromagnetic waves. Such spectra are attributed to optically active vibrational modes. In these studies the DFT calculations were implemented using the computer program GAUSSIAN09 (G09) [2].

The report is organized as follows. First, a general review of vibrational analysis needed for calculation of absorption spectra is presented. Second, DFT calculations of energy-minimized structures and vibration resonance structure for PCE-nH₂O, TCE-nH₂O, DCE-nH₂O and VC-nH₂O molecular clusters are presented. The vibration resonance structure of these molecular clusters provides estimates of their IR spectra and interpretation of spectral features with respect to molecular structure. Finally, a conclusion is presented.

Figure 1. Transformation sequence for PCE to Ethene.

Calculation of Absorption Spectra using DFT

This section describes the formalism underlying DFT calculations and the procedure for calculation of absorption spectra corresponding to vibrational states, which the present study considers. Although descriptions of this formalism have been presented many times previously, a review of vibrational analysis needed for calculation of absorption spectra is given again for

completeness. The DFT software GAUSSIAN09 (G09) can be used to compute an approximation of the IR absorption spectrum of a molecule or molecule [2, 3]. This program calculates vibrational frequencies by determining second derivatives of the energy with respect to the Cartesian nuclear coordinates, and then transforming to mass-weighted coordinates at a stationary point of the geometry. The IR absorption spectrum is obtained using density functional theory to compute the ground state electronic structure in the Born-Oppenheimer approximation using Kohn-Sham density functional theory [4-9]. GAUSSIAN uses specified orbital basis functions to describe the electronic wavefunctions and density. For a given set of nuclear positions, the calculation directly gives the electronic charge density of the molecule, the potential energy V , and the displacements in Cartesian coordinates of each atom. The procedure for vibrational analysis used in GAUSSIAN is described in reference [3], and is reviewed in reference [9].

The procedure followed by GAUSSIAN is based on the fact the vibrational spectrum depends on the Hessian matrix \mathbf{f}_{CART} , which is constructed using the second partial derivatives of the potential energy V with respect to displacements of the atoms in Cartesian coordinates. Accordingly, the elements of the $3N \times 3N$ matrix \mathbf{f}_{CART} are given by

$$f_{\text{CART}ij} = \left(\frac{\partial^2 V}{\partial \xi_i \partial \xi_j} \right)_0 \quad (\text{Eq 1})$$

where $\{\xi_1, \xi_2, \xi_3, \xi_4, \xi_5, \xi_6, \dots, \xi_{3N}\} = \{\Delta x_1, \Delta y_1, \Delta z_1, \Delta x_2, \Delta y_2, \Delta z_2, \dots, \Delta z_N\}$, which are displacements in Cartesian coordinates, and N is the number of atoms. As discussed above, the zero subscript in Eq.(1) indicates that the derivatives are taken at the equilibrium positions of the atoms, and that the first derivatives are zero. Given the Hessian matrix defined by Eq.(1) the operations for calculation of the vibrational spectrum require that the Hessian matrix Eq.(1) be transformed to mass-weighted Cartesian coordinates according to the relation

$$f_{\text{MWC}ij} = \frac{f_{\text{CART}ij}}{\sqrt{m_i m_j}} = \left(\frac{\partial^2 V}{\partial q_i \partial q_j} \right)_0, \quad (\text{Eq 2})$$

where $\{q_1, q_2, q_3, q_4, q_5, q_6, \dots, q_{3N}\} = \{\sqrt{m_1} \Delta x_1, \sqrt{m_1} \Delta y_1, \sqrt{m_1} \Delta z_1, \sqrt{m_2} \Delta x_2, \sqrt{m_2} \Delta y_2, \sqrt{m_2} \Delta z_2, \dots, \sqrt{m_N} \Delta z_N\}$ are the mass-weighted Cartesian coordinates. GAUSSIAN computes the energy second derivatives Eq.(2), thus computing the forces for displacement perturbations of each atom

along each Cartesian direction. The first derivatives of the dipole moment with respect to atomic positions $\partial \vec{\mu} / \partial \xi_i$ are also computed. Each vibrational eigenmode leads to one peak in the absorption spectrum, at a frequency equal to the mode's eigenfrequency ν_n . The absorption intensity corresponding to a particular eigenmode n , whose eigenfrequency is ν_n , is given by

$$I_n = \frac{\pi}{3c} \left| \sum_{i=1}^{3N} \frac{\partial \vec{\mu}}{\partial \xi_i} l_{\text{CART}im} \right|^2, \quad (\text{Eq 3})$$

where \mathbf{l}_{CART} is the matrix whose elements are the displacements of the atoms in Cartesian coordinates, and is determined as follows. First,

$$\mathbf{l}_{\text{CART}} = \mathbf{M} \mathbf{l}_{\text{MWC}}, \quad (\text{Eq 4})$$

where \mathbf{l}_{MWC} is the matrix whose elements are the displacements of the atoms in mass-weighted Cartesian coordinates and \mathbf{M} is a diagonal matrix defined by the elements

$$M_{ii} = \frac{1}{\sqrt{m_i}}. \quad (\text{Eq 5})$$

The matrix \mathbf{l}_{MWC} is needed to diagonalize \mathbf{f}_{MWC} defined by Eq.(2) such that

$$(\mathbf{l}_{\text{MWC}})^T \mathbf{f}_{\text{MWC}} (\mathbf{l}_{\text{MWC}}) = \mathbf{\Lambda}, \quad (\text{Eq 6})$$

where $\mathbf{\Lambda}$ is the diagonal matrix with eigenvalues λ_i . The procedure for diagonalizing Eq.(6) consists of the operations

$$\mathbf{f}_{\text{INT}} = (\mathbf{D})^T \mathbf{f}_{\text{MWC}} (\mathbf{D}) \quad (\text{Eq 7})$$

and

$$(\mathbf{L})^T \mathbf{f}_{\text{MWC}} (\mathbf{L}) = \mathbf{\Lambda}, \quad (\text{Eq 8})$$

where \mathbf{D} is a matrix transformation to coordinates where rotation and translation have been separated out and \mathbf{L} is the transformation matrix composed of eigenvectors calculated according to Eq.(8). The eigenfrequencies in units of (cm^{-1}) are calculated using the eigenvalues λ_n by the expression

$$\nu_{n0} = \frac{\sqrt{\lambda_n}}{2\pi c}, \quad (\text{Eq 9})$$

where c is the speed of light. The elements of \mathbf{l}_{CART} are given by

$$l_{\text{CART}ki} = \sum_{j=1}^{3N} \frac{D_k L_{ji}}{\sqrt{m_j}}, \quad (\text{Eq 10})$$

where $k, i=1, \dots, 3N$, and the column vectors of these elements are the normal modes in Cartesian coordinates.

The intensity Eq.(3) must then be multiplied by the number density of molecules to give an absorption-line intensity in the non-interacting molecule approximation. It follows that the absorption spectrum calculated by GAUSSIAN is a sum of delta functions, whose line positions and coefficients correspond to the vibrational-transition frequencies and the absorption-line intensities, respectively. It should be noted that, in principle, these spectral components must be broadened and shifted to account for anharmonic effects such as finite mode lifetimes and inter-mode couplings.

Energy-Minimized Structures and Their IR Spectra

Results of a computational investigation using DFT concerning PCE-nH₂O, TCE-nH₂O, DCE-nH₂O and VC-nH₂O molecular structures are presented. These results include the energy-minimized configuration of these molecular structures, their ground-state oscillation frequencies and their IR intensities. The DFT calculations have resulted in molecular cluster geometries corresponding to energetically stable structures. For these calculations geometry energy optimization and vibrational analysis was effected using the DFT model B3LYP [10,11] and basis functions 6-311+G(d) [12,13]. These basis functions designate the 6-311G basis set supplemented by diffuse functions, indicated by the sign +, and polarization functions (d), having one set of d functions on heavy atoms [14]. Graphical representations of molecular geometries for stable molecular clusters consisting of PCE-nH₂O, TCE-nH₂O, DCE-nH₂O and VC-nH₂O and their IR spectra are shown in Figs. (2) through (54). The ground-state energies of these molecular clusters are given in Table 1. IR intensities as a function of frequency, for the molecular clusters and IR spectra shown in Figs. (2) through (54), are given in Tables 2 through 7 of appendices 1 through 6, respectively.

Conclusion

The DFT calculated absorption spectra given here provide information concerning molecular level dielectric response structure. The calculations of vibrational excited states associated with PCE-nH₂O, TCE-nH₂O, DCE-nH₂O and VC-nH₂O molecular clusters using DFT

are meant to serve as reasonable estimates of molecular level response characteristics, providing interpretation of dielectric response features with respect to molecular structure, for comparison with experimental measurements. We have studied here PCE-nH₂O, TCE-nH₂O, DCE-nH₂O and VC-nH₂O molecular clusters in order to quantify interpretation of their absorption spectra.
